

Fukushima disaster - New data on the contamination of Japanese children

ACRO has again analyzed the urine of Japanese children and the results are unambiguous: all children in Fukushima were or are contaminated, while we have not found any contamination in the urine of children in Tokyo and surroundings.

Fukushima children who were evacuated by their parents saw their contamination of the urine drop. More than four months after the massive discharges of radioactivity into the environment, others are still contaminated, although their parents do their best to reduce this contamination. It is likely that this is due to food.

The results are detailed with comments on our website: <http://acro.eu.org>

While the tests performed by the Japanese authorities gives about one child from Fukushima out two that is contaminated, we get 100%. This reflects the fact that the official measurements are not accurate enough and did not detect all contaminations.

It is important to conduct an accurate, systematic and regular monitoring of internal contamination of children from Fukushima. Families must have access to the measurement of radioactivity to help them reduce this contamination.
